Tangential jet flush model

One flush in milliseconds: compare designs quickly, then check the best ones with CFD

ILLUSTRATIVE ESTIMATES, DEFAULT DESIGN

88 %

of the bowl wall above the waterline cleaned

99 %

of a 250 g solid test load removed

4.5 L

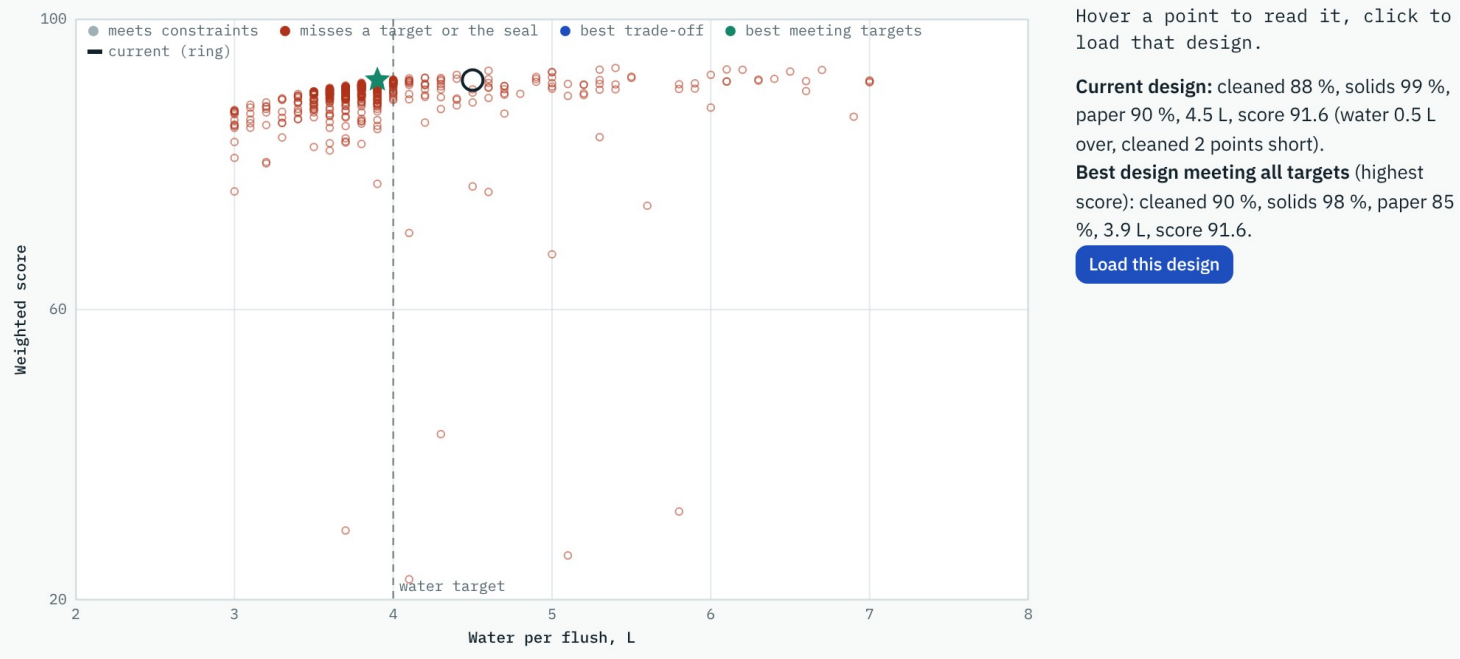

water per flush, EU washdown, full flush

fintlp.github.io/jet-flush-model

Illustrative estimates from a reduced-order model. Coefficients are not yet calibrated against CFD or rig data, so results show trends between designs, not validated values.

AI lab: let the model search

Three ways AI works with the physics model, all running in the browser

Each dot is one simulated flush; red rings miss a target. The blue curve is the best trade-off between score and water, and the green star is the best design that meets all targets.

5–20 ms
physics model, per flush

≈ 5 µs
neural surrogate, per design

minutes to hours
PreonLab or CFD, rough estimate

1 Design optimiser

Finds the best settings you allow, or a design that meets targets such as at most 4.0 L and at least 90 % cleaned. About 540 flushes in 4 seconds.

2 Neural surrogate

Learns the model from 300 flushes and answers roughly a thousand times faster. In practice it would be trained on PreonLab runs.

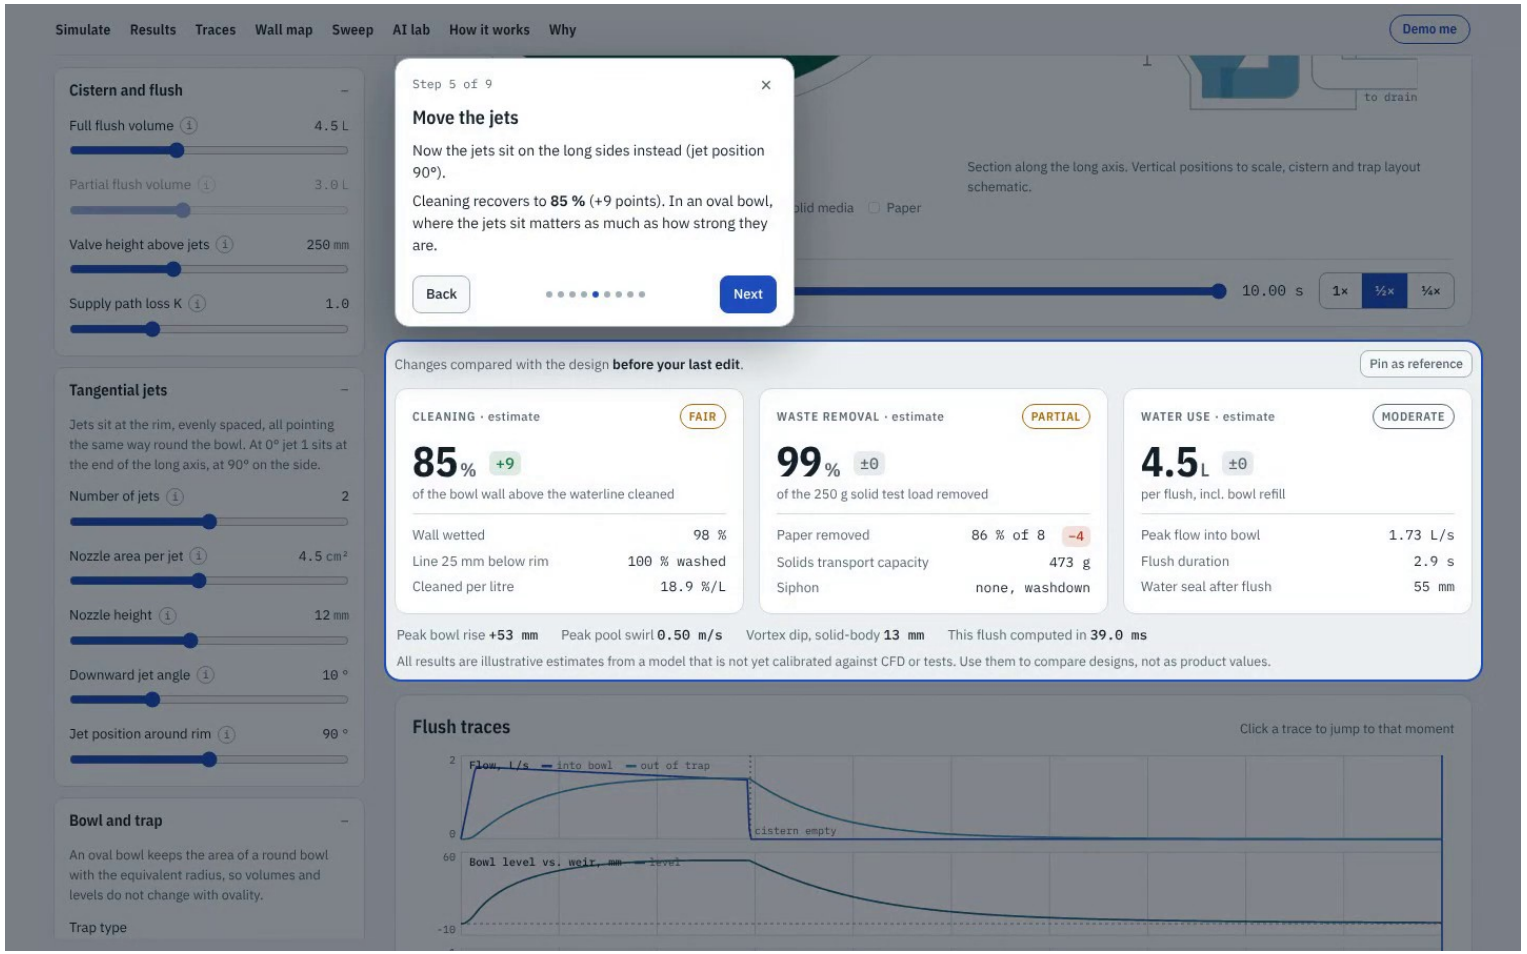

3 Hybrid calibration

Fits the model to reference runs and corrects the rest with data. On synthetic test data it cuts the error on unseen designs by about two to eight times.

Results come from the uncalibrated model: suggestions are candidates for a CFD or rig check, not final answers. The calibration demo uses synthetic reference data.

Guided demo in one minute

Play a flush, make the bowl oval, let the AI find a better design, all live in the browser

88 % → 76 %

cleaning when the bowl turns oval, jets at the ends

76 % → 85 %

after moving the jets to the long sides

90 % at 4.0 L

AI lab design: more cleaning, 0.5 L less water
